

Coffee Supply Report

This report looks at how the supply of coffee changed during the last year and what buyers can do about it. The main finding is that prices are set by a few large example markets, while the smaller producers follow them with a delay of several weeks.

Main findings

- Prices rose in every region except the north
- Shipping times are back to normal
- Stocks are still lower than a year ago

Prices by region

Region	Price	Change
North	3.10	-2%
South	3.80	+9%
East	3.55	+4%

The tables above show the average price paid by buyers in each region, and the paragraph that follows carries on to the next page without any closing punctuation so that it

continues here, in lower case, and ends with a full stop.

Conclusion

Buyers should sign longer contracts with small producers. Smaller producers react slowly, so a fixed price protects both sides.

Appendix: the harvest

The first column tells how the harvest began in the spring and how the early rains helped the plants grow well before the summer heat arrived in the valley. Workers picked the beans by hand and sorted them on long tables, one by one, so that only the ripest fruit went into the bags that were sent to the port.

The second column explains what came next: the bags travelled by truck and then by ship, and the whole trip took about five weeks when the weather was good. Buyers in the north received the coffee first, while the southern markets waited a little longer for the same shipment because of the port queues.
